We can train a model for classification using a regression loss such as the MSE using a "one-hot vector" encoding: given a training set

$$(x_n,y_n)\in\mathbb{R}^D\times\{1,\ldots,C\},\ n=1,\ldots,N,$$

we would convert the labels into a tensor  $z \in \mathbb{R}^{N \times C}$ , with

$$\forall n, z_{n,m} = \begin{cases} 1 & \text{if } m = y_n \\ 0 & \text{otherwise.} \end{cases}$$

We can train a model for classification using a regression loss such as the MSE using a "one-hot vector" encoding: given a training set

$$(x_n, y_n) \in \mathbb{R}^D \times \{1, \dots, C\}, \ n = 1, \dots, N,$$

we would convert the labels into a tensor  $z \in \mathbb{R}^{N \times C}$ , with

$$\forall n, z_{n,m} = \left\{ \begin{array}{ll} 1 & \text{if } m = y_n \\ 0 & \text{otherwise.} \end{array} \right.$$

For instance, with N=5 and C=3, we would have

$$\begin{pmatrix} 2\\1\\1\\3\\2 \end{pmatrix} \Rightarrow \begin{pmatrix} 0 & 1 & 0\\1 & 0 & 0\\1 & 0 & 0\\0 & 0 & 1\\0 & 1 & 0 \end{pmatrix}.$$

We can train a model for classification using a regression loss such as the MSE using a "one-hot vector" encoding: given a training set

$$(x_n, y_n) \in \mathbb{R}^D \times \{1, \dots, C\}, \ n = 1, \dots, N,$$

we would convert the labels into a tensor  $z \in \mathbb{R}^{N \times C}$ , with

$$\forall n, z_{n,m} = \left\{ \begin{array}{ll} 1 & \text{if } m = y_n \\ 0 & \text{otherwise.} \end{array} \right.$$

For instance, with N=5 and C=3, we would have

$$\begin{pmatrix} 2\\1\\1\\3\\2 \end{pmatrix} \Rightarrow \begin{pmatrix} 0 & 1 & 0\\1 & 0 & 0\\1 & 0 & 0\\0 & 0 & 1\\0 & 1 & 0 \end{pmatrix}.$$

Training can be achieved by matching the output of the model with these binary values in a MSE sense.

As we will see, the criterion of choice for classification is the cross-entropy.

$$P(Y = y \mid X = x, W = w) = \frac{1}{Z} \exp f_y(x; w) = \frac{\exp f_y(x; w)}{\sum_k \exp f_k(x; w)}$$

$$P(Y = y \mid X = x, W = w) = \frac{1}{Z} \exp f_y(x; w) = \frac{\exp f_y(x; w)}{\sum_k \exp f_k(x; w)},$$

from which

$$\begin{split} \log \mu_W \big( w \mid \mathcal{D} &= \mathbf{d} \big) \\ &= \log \frac{\mu_{\mathcal{D}} \big( \mathbf{d} \mid W = w \big) \, \mu_W \big( w \big)}{\mu_{\mathcal{D}} \big( \mathbf{d} \big)} \\ &= \log \mu_{\mathcal{D}} \big( \mathbf{d} \mid W = w \big) + \log \mu_W \big( w \big) - \log Z \\ &= \sum_n \log \mu_{\mathcal{D}} \big( x_n, y_n \mid W = w \big) + \log \mu_W \big( w \big) - \log Z \\ &= \sum_n \log P \big( Y = y_n \mid X = x_n, W = w \big) + \log \mu_W \big( w \big) - \log Z' \\ &= \sum_n \log \left( \frac{\exp f_{y_n} \big( x; w \big)}{\sum_k \exp f_k \big( x; w \big)} \right) \, + \, \log \mu_W \big( w \big) - \log Z'. \end{split}$$

$$P(Y = y \mid X = x, W = w) = \frac{1}{Z} \exp f_y(x; w) = \frac{\exp f_y(x; w)}{\sum_k \exp f_k(x; w)},$$

from which

$$\begin{split} \log \mu_W \big( w \mid \mathscr{D} &= \mathbf{d} \big) \\ &= \log \frac{\mu_{\mathscr{D}} (\mathbf{d} \mid W = w) \, \mu_W (w)}{\mu_{\mathscr{D}} (\mathbf{d})} \\ &= \log \mu_{\mathscr{D}} (\mathbf{d} \mid W = w) + \log \mu_W (w) - \log Z \\ &= \sum_n \log \mu_{\mathscr{D}} (x_n, y_n \mid W = w) + \log \mu_W (w) - \log Z \\ &= \sum_n \log P(Y = y_n \mid X = x_n, W = w) + \log \mu_W (w) - \log Z' \\ &= \sum_n \log \left( \frac{\exp f_{y_n}(x; w)}{\sum_k \exp f_k(x; w)} \right) + \log \mu_W (w) - \log Z'. \end{split}$$

$$P(Y = y \mid X = x, W = w) = \frac{1}{Z} \exp f_y(x; w) = \frac{\exp f_y(x; w)}{\sum_k \exp f_k(x; w)},$$

from which

$$\begin{split} \log \mu_W \big( w \mid \mathscr{D} &= \mathbf{d} \big) \\ &= \log \frac{\mu_{\mathscr{D}} \big( \mathbf{d} \mid W = w \big) \, \mu_W \big( w \big)}{\mu_{\mathscr{D}} \big( \mathbf{d} \big)} \\ &= \log \mu_{\mathscr{D}} \big( \mathbf{d} \mid W = w \big) + \log \mu_W \big( w \big) - \log Z \\ &= \sum_n \log \mu_{\mathscr{D}} \big( x_n, y_n \mid W = w \big) + \log \mu_W \big( w \big) - \log Z \\ &= \sum_n \log P \big( Y = y_n \mid X = x_n, W = w \big) + \log \mu_W \big( w \big) - \log Z' \\ &= \sum_n \log \left( \frac{\exp f_{y_n} \big( x; w \big)}{\sum_k \exp f_k \big( x; w \big)} \right) + \underbrace{\log \mu_W \big( w \big)}_{\text{Depends on the outputs}} - \log Z'. \end{split}$$

$$\mathscr{L}(w) = -\frac{1}{N} \sum_{n=1}^{N} \log \left( \frac{\exp f_{y_n}(x_n; w)}{\sum_{k} \exp f_k(x_n; w)} \right).$$

$$\mathscr{L}(w) = -\frac{1}{N} \sum_{n=1}^{N} \log \underbrace{\left(\frac{\exp f_{y_n}(x_n; w)}{\sum_{k} \exp f_k(x_n; w)}\right)}_{\hat{P}_w(Y = y_n | X = x_n)}.$$

Given two distributions p and q, their cross-entropy is defined as

$$\mathbb{H}(p,q) = -\sum_{k} p(k) \log q(k),$$

with the convention that  $0 \log 0 = 0$ .

$$\mathscr{L}(w) = -\frac{1}{N} \sum_{n=1}^{N} \log \underbrace{\left(\frac{\exp f_{y_n}(x_n; w)}{\sum_{k} \exp f_k(x_n; w)}\right)}_{\hat{P}_w(Y = y_n | X = x_n)}.$$

Given two distributions p and q, their **cross-entropy** is defined as

$$\mathbb{H}(p,q) = -\sum_{k} p(k) \log q(k),$$

with the convention that  $0 \log 0 = 0$ . So we can re-write

$$-\log\left(\frac{\exp f_{y_n}(x_n; w)}{\sum_k \exp f_k(x_n; w)}\right) = -\log \hat{P}_w(Y = y_n \mid X = x_n)$$

$$= -\sum_k \delta_{y_n}(k) \log \hat{P}_w(Y = k \mid X = x_n)$$

$$= \mathbb{H}\left(\delta_{y_n}, \hat{P}_w(Y = \cdot \mid X = x_n)\right).$$

$$\mathscr{L}(w) = -\frac{1}{N} \sum_{n=1}^{N} \log \underbrace{\left(\frac{\exp f_{y_n}(x_n; w)}{\sum_k \exp f_k(x_n; w)}\right)}_{\hat{P}_w(Y = y_n | X = x_n)}.$$

Given two distributions p and q, their **cross-entropy** is defined as

$$\mathbb{H}(p,q) = -\sum_{k} p(k) \log q(k),$$

with the convention that  $0 \log 0 = 0$ . So we can re-write

$$-\log\left(\frac{\exp f_{y_n}(x_n; w)}{\sum_k \exp f_k(x_n; w)}\right) = -\log \hat{P}_w(Y = y_n \mid X = x_n)$$

$$= -\sum_k \delta_{y_n}(k) \log \hat{P}_w(Y = k \mid X = x_n)$$

$$= \mathbb{H}\left(\delta_{y_n}, \hat{P}_w(Y = \cdot \mid X = x_n)\right).$$

So  $\mathscr L$  above is the average of the cross-entropy between the deterministic "true" posterior  $\delta_{y_n}$  and the estimated  $\hat{P}_w(Y=\cdot\mid X=x_n)$ .

This is precisely the value of torch.nn.CrossEntropyLoss.

This is precisely the value of torch.nn.CrossEntropyLoss.

```
>>> f = torch.tensor([[-1., -3., 4.], [-3., 3., -1.]])
>>> target = torch.tensor([0, 1])
>>> criterion = torch.nn.CrossEntropyLoss()
>>> criterion(f, target)
tensor(2.5141)
```

### and indeed

$$-\frac{1}{2} \left( \log \frac{e^{-1}}{e^{-1} + e^{-3} + e^4} + \log \frac{e^3}{e^{-3} + e^3 + e^{-1}} \right) \simeq 2.5141.$$

This is precisely the value of torch.nn.CrossEntropyLoss.

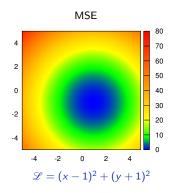

```
>>> f = torch.tensor([[-1., -3., 4.], [-3., 3., -1.]])
>>> target = torch.tensor([0, 1])
>>> criterion = torch.nn.CrossEntropyLoss()
>>> criterion(f, target)
tensor(2.5141)
```

and indeed

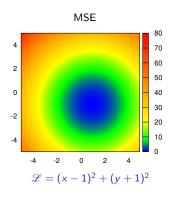

$$-\frac{1}{2}\left(\log\frac{e^{-1}}{e^{-1}+e^{-3}+e^4}+\log\frac{e^3}{e^{-3}+e^3+e^{-1}}\right)\simeq 2.5141.$$

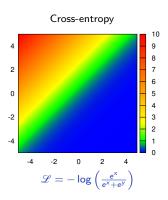

The range of values is 0 for perfectly classified samples,  $\log(C)$  if the posterior is uniform, and up to  $+\infty$  if the posterior distribution is "worse" than uniform.

Let's consider the loss for a single sample in a two-class problem, with a predictor with two output values. The  $\times$  axis here is the activation of the correct output unit, and the y axis is the activation of the other one.

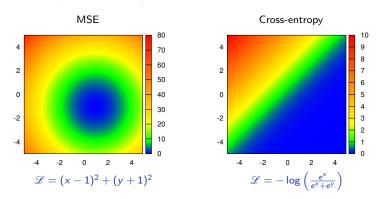

Let's consider the loss for a single sample in a two-class problem, with a predictor with two output values. The x axis here is the activation of the correct output unit, and the y axis is the activation of the other one.

Let's consider the loss for a single sample in a two-class problem, with a predictor with two output values. The x axis here is the activation of the correct output unit, and the y axis is the activation of the other one.

MSE incorrectly penalizes outputs which are perfectly valid for prediction, contrary to cross-entropy.

The cross-entropy loss can be seen as the composition of a "log soft-max" to normalize the [logit] scores into logs of probabilities

$$(\alpha_1, \dots, \alpha_C) \mapsto \left(\log \frac{\exp \alpha_1}{\sum_k \exp \alpha_k}, \dots, \log \frac{\exp \alpha_C}{\sum_k \exp \alpha_k}\right),$$

which can be done with the torch.nn.LogSoftmax module

The cross-entropy loss can be seen as the composition of a "log soft-max" to normalize the [logit] scores into logs of probabilities

$$(\alpha_1, \dots, \alpha_C) \mapsto \left(\log \frac{\exp \alpha_1}{\sum_k \exp \alpha_k}, \dots, \log \frac{\exp \alpha_C}{\sum_k \exp \alpha_k}\right),$$

which can be done with the torch.nn.LogSoftmax module, and a read-out of the normalized score of the correct class

$$\mathscr{L}(w) = -\frac{1}{N} \sum_{n=1}^{N} f_{y_n}(x_n; w),$$

which is implemented by the torch.nn.NLLLoss criterion.

The cross-entropy loss can be seen as the composition of a "log soft-max" to normalize the [logit] scores into logs of probabilities

$$(\alpha_1, \dots, \alpha_C) \mapsto \left(\log \frac{\exp \alpha_1}{\sum_k \exp \alpha_k}, \dots, \log \frac{\exp \alpha_C}{\sum_k \exp \alpha_k}\right),$$

which can be done with the torch.nn.LogSoftmax module, and a read-out of the normalized score of the correct class

$$\mathscr{L}(w) = -\frac{1}{N} \sum_{n=1}^{N} f_{y_n}(x_n; w),$$

which is implemented by the torch.nn.NLLLoss criterion.

```
>>> f = torch.tensor([[-1., -3., 4.], [-3., 3., -1.]])
>>> target = torch.tensor([0, 1])
>>> model = nn.LogSoftmax(dim = 1)
>>> criterion = torch.nn.NLLLoss()
>>> criterion(model(f), target)
tensor(2.5141)
```

Hence, if a network should compute log-probabilities, it may have a torch.nn.LogSoftmax final layer, and be trained with torch.nn.NLLLoss.

The mapping

$$(\alpha_1, \dots, \alpha_C) \mapsto \left( \frac{\exp \alpha_1}{\sum_k \exp \alpha_k}, \dots, \frac{\exp \alpha_C}{\sum_k \exp \alpha_k} \right)$$

is called soft-max since it computes a "soft arg-max Boolean label."

#### The mapping

$$(\alpha_1, \dots, \alpha_C) \mapsto \left( \frac{\exp \alpha_1}{\sum_k \exp \alpha_k}, \dots, \frac{\exp \alpha_C}{\sum_k \exp \alpha_k} \right)$$

is called soft-max since it computes a "soft arg-max Boolean label."

### PyTorch provides many other criteria, among which

- torch.nn.MSELoss
- torch.nn.CrossEntropyLoss
- torch.nn.NLLLoss
- torch.nn.L1Loss
- torch.nn.NLLLoss2d
- torch.nn.MultiMarginLoss
