We saw that training consists of finding the model parameters minimizing an empirical risk or loss, for instance the mean-squared error (MSE) $\,$

$$\mathscr{L}(w,b) = \frac{1}{N} \sum_{n} (f(x_n; w, b) - y_n)^2.$$

Other losses are more fitting for classification, certain regression problems, or density estimation. We will come back to this.

We saw that training consists of finding the model parameters minimizing an empirical risk or loss, for instance the mean-squared error (MSE)

$$\mathscr{L}(w,b) = \frac{1}{N} \sum_{n} (f(x_n; w, b) - y_n)^2.$$

Other losses are more fitting for classification, certain regression problems, or density estimation. We will come back to this.

So far we minimized the loss either with an analytic solution for the MSE, or with ad hoc recipes for the empirical error rate (k-NN and perceptron).

There is generally no ad hoc method. The logistic regression for instance

$$P_w(Y = 1 \mid X = x) = \sigma(w \cdot x + b), \text{ with } \sigma(x) = \frac{1}{1 + e^{-x}}$$

leads to the loss

$$\mathscr{L}(w,b) = -\sum_{n} \log \sigma(y_n(w \cdot x_n + b))$$

which cannot be minimized analytically.

There is generally no ad hoc method. The logistic regression for instance

$$P_w(Y = 1 \mid X = x) = \sigma(w \cdot x + b), \text{ with } \sigma(x) = \frac{1}{1 + e^{-x}}$$

leads to the loss

$$\mathscr{L}(w,b) = -\sum_{n} \log \sigma(y_n(w \cdot x_n + b))$$

which cannot be minimized analytically.

The general minimization method used in such a case is the gradient descent.

Given a functional

$$f: \mathbb{R}^D \to \mathbb{R}$$

 $x \mapsto f(x_1, \dots, x_D),$

its gradient is the mapping

$$\nabla f: \mathbb{R}^D \to \mathbb{R}^D$$
$$x \mapsto \left(\frac{\partial f}{\partial x_1}(x), \dots, \frac{\partial f}{\partial x_D}(x)\right).$$

To minimize a functional

$$\mathcal{L}:\mathbb{R}^D\to\mathbb{R}$$

the gradient descent uses local linear information to iteratively move toward a (local) minimum.

To minimize a functional

$$\mathcal{L}:\mathbb{R}^D\to\mathbb{R}$$

the gradient descent uses local linear information to iteratively move toward a (local) minimum.

For $w_0 \in \mathbb{R}^D$, consider an approximation of \mathscr{L} around w_0

$$\widetilde{\mathscr{L}}_{w_0}(w) = \mathscr{L}(w_0) + \nabla \mathscr{L}(w_0)^T (w - w_0) + \frac{1}{2n} \|w - w_0\|^2.$$

Note that the chosen quadratic term does not depend on \mathcal{L} .

To minimize a functional

$$\mathcal{L}:\mathbb{R}^D\to\mathbb{R}$$

the gradient descent uses local linear information to iteratively move toward a (local) minimum.

For $w_0 \in \mathbb{R}^D$, consider an approximation of \mathscr{L} around w_0

$$\mathscr{\tilde{Z}}_{w_0}(w) = \mathscr{Z}(w_0) + \nabla \mathscr{Z}(w_0)^T (w - w_0) + \frac{1}{2n} \|w - w_0\|^2.$$

Note that the chosen quadratic term does not depend on \mathcal{L} .

We have

$$abla ilde{\mathscr{L}}_{w_0}(w) =
abla \mathscr{L}(w_0) + rac{1}{n}(w-w_0),$$

which leads to

$$\underset{w}{\operatorname{argmin}}\,\tilde{\mathscr{L}}_{w_0}(w)=w_0-\eta\nabla\mathscr{L}(w_0).$$

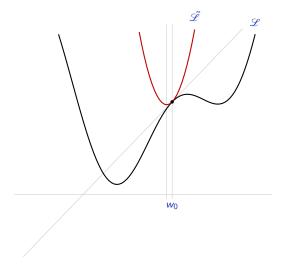

The resulting iterative rule, which goes to the minimum of the approximation at the current location, takes the form:

$$w_{t+1} = w_t - \eta \nabla \mathcal{L}(w_t).$$

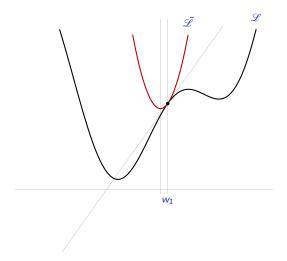

Which corresponds intuitively to "following the steepest descent".

This finds a **local** minimum, and the choices of w_0 and η are important.

We saw that the minimum of the logistic regression loss

$$\mathscr{L}(w,b) = -\sum_{n} \log \sigma(y_n(w \cdot x_n + b))$$

does not have an analytic form.

We can derive

$$\frac{\partial \mathcal{L}}{\partial b} = -\sum_{n} \underbrace{y_{n} \, \sigma(-y_{n}(w \cdot x_{n} + b))}_{u_{n}},$$

$$\forall d, \ \frac{\partial \mathcal{L}}{\partial w_{d}} = -\sum_{n} \underbrace{x_{n,d} \, y_{n} \, \sigma(-y_{n}(w \cdot x_{n} + b))}_{v_{n,d}},$$

We can derive

$$\frac{\partial \mathcal{L}}{\partial b} = -\sum_{n} \underbrace{y_{n} \, \sigma(-y_{n}(w \cdot x_{n} + b))}_{u_{n}},$$

$$\forall d, \ \frac{\partial \mathcal{L}}{\partial w_{d}} = -\sum_{n} \underbrace{x_{n,d} \, y_{n} \, \sigma(-y_{n}(w \cdot x_{n} + b))}_{v_{n,d}},$$

which can be implemented as

```
def gradient(x, y, w, b):
    u = y * ( - y * (x.mv(w) + b)).sigmoid_()
    v = x * u.view(-1, 1) # Broadcasting
    return - v.sum(0), - u.sum()
```

We can derive

$$\frac{\partial \mathcal{L}}{\partial b} = -\sum_{n} \underbrace{y_{n} \, \sigma(-y_{n}(w \cdot x_{n} + b))}_{u_{n}},$$

$$\forall d, \ \frac{\partial \mathcal{L}}{\partial w_{d}} = -\sum_{n} \underbrace{x_{n,d} \, y_{n} \, \sigma(-y_{n}(w \cdot x_{n} + b))}_{v_{n,d}},$$

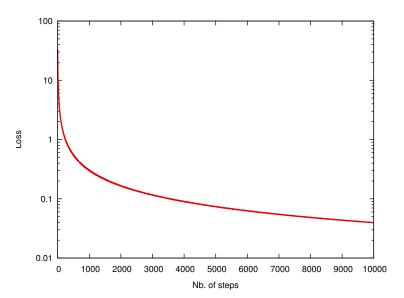

which can be implemented as

```
def gradient(x, y, w, b):
    u = y * ( - y * (x.mv(w) + b)).sigmoid_()
    v = x * u.view(-1, 1) # Broadcasting
    return - v.sum(0), - u.sum()
```

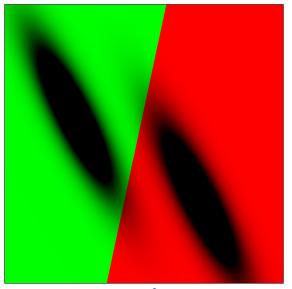

and the gradient descent as

```
w, b = torch.empty(x.size(1)).normal_(), 0
eta = 1e-1

for k in range(nb_iterations):
    dw, db = gradient(x, y, w, b)
    w -= eta * dw
    b -= eta * db
```

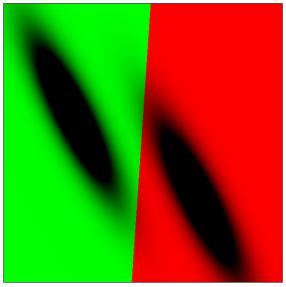

With 100 training points and $\eta = 10^{-1}$.

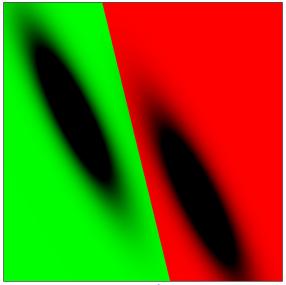

13 / 13

With 100 training points and $\eta = 10^{-1}$.

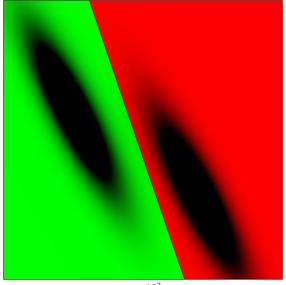

n = 10

With 100 training points and $\eta = 10^{-1}$.

 $n = 10^2$

With 100 training points and $\eta = 10^{-1}$.

 $n = 10^3$

With 100 training points and $\eta = 10^{-1}$.

 $n = 10^4$
